The invention provides vectors (such as viral vectors, plasmid

vectors or phagemids) comprising: (a) a heterologous nucleotide sequence encoding an antigenic polypeptide from a pathogen (such as viral, bacterial, parasitic or fungal); (b) a nucleotide sequence encoding a protease inhibitor (such as human PI31); a nucleotide sequence for a constitutive, regulatable, and/or cell/tissue-specific promoter; and (d) a nucleotide sequence encoding an inhibitory RNA mols., specifically an antisense human HERNA oligonucleotides. The invention also provides vectors comprising a nucleotide sequence encoding CIITA, a polypeptide that stimulates the expression of MHC The invention further provides the use of said class II genes. vectors as vaccines in production of an immune response (humoral) to said antigens in an animal, such as human, wherein said vaccination may be against a viral, fungal, bacterial or parasitic disorder. Still further, the invention relates: (a) using said vectors in production of antibodies, wherein said antibodies may be of therapeutic and/or of diagnostic use; (b) that said vectors may be adapted for expression of humanized or chimeric antibodies; and (c) that said vectors may be used to used to immunize animals for production of hybridomas expressing a monoclonal antibody against antigen of interest. Finally, the invention provides the cDNA sequences of mouse CIITA, and human PI31, and partial cDNA sequence of human HERNA helicase. The invention related that the use of said vectors containing said sequences can be used to enhance secretion of translated immunogen, and enhance DNA vaccination bias away from an MHC class I event towards MHC class II event. In the examples, the invention presented the construction of two vectors, pcDNAFinal and pcDNA6TR-IRES-CIITA, wherein pcDNAFinal contains nucleotide sequences encoding immunogen parathyroid hormone-related protein (PTHrP), antisense HERNA mRNA, PI31 and CD4+ T-cell epitope from lymphocytic choriomeningitis virus and wherein pcDNA6TR-IRES-CIITA encodes CIITA. Specifically, the invention related that: (a) antisense HERNA RNA can increase the transcriptional efficiency of vectors resulting in greater levels of transgene expression; (b) PI31 can inhibit proteasome digestion of recombinant antigen making it more assessable to MHC class II antigens; (c) inclusion of CD4+ T-cell epitope ensured that degraded immunogen-MHC class II complex bound to CD4+ T cells; and (d) inclusion of CIITA protein allowed for over-expression of MHC class II antigens.

                               English
LANGUAGE:
      The mosquito-borne malaria parasite Plasmodium
      falciparum kills an estimated 0.7-2.7 million people every year,
      primarily children in sub-Saharan Africa. Without effective
      interventions, a variety of factors-including the spread of
      parasites resistant to antimalarial drugs and the increasing
      insecticide resistance of mosquitoes-may cause the number of malaria
```

cases to double over the next two decades. To stimulate basic research and facilitate the development of new drugs and vaccines, the genome of Plasmodium falciparum clone 3D7 has been sequenced using a chromosome-by-chromosome shotgun strategy. This report describes nucleotide sequences of chromosomes 10, 11 and 14, and a re-anal. of the chromosome 2 sequence. These chromosomes represent about 35% of the 23-megabase P. falciparum genome. The sequences are deposited in GenBank/EMBL/DDBJ under accession nos. AE001362.2 (chromosome 2),  $^{\sim}$  AE014185 (chromosome\_10), AE014186 (chromosome 11), and AE014187 $^{\circ}$ (chromosome 14).

We have sequenced six overlapping clones from a library of bacterial artificial chromosome (BAC) clones derived from a laboratory strain of the mosquito, Anopheles gambiae, the major vector of human malaria in Africa. The resulting uninterrupted 528-kb sequence is from the 8C region of the mosquito 2R chromosome, at or very near the major refractoriness locus associated with melanotic encapsulation of parasites. This sequence represents the first extensive view of the mosquito genome structure encompassing 48 genes. Genomic comparison reveals that the majority of the orthologues are found in six microsyntenic clusters in Drosophila melanogaster. A BAC clone that is wholly contained within this region demonstrates the existence of a remarkable degree of local polymorphism in this species, which may prove important for its population structure and vectorial capacity.

DOCUMENT TYPE: Journal LANGUAGE: English

We have obtained a full-length P type ATPase sequence

(PfATP4) encoded by Plasmodium falciparum and expressed PfATP4 in Xenopus laevis oocytes to study its function.

Comparison of the hitherto incomplete open reading frame with other Ca2+-ATPase sequences reveals that PfATP4 differs

significantly from previously defined categories. The Ca2+-dependent ATPase activity of PfATP4 is

stimulated by a much broader range of [Ca2+] free (3.2-320  $\mu M)$  than are an avian SERCA1 pump or rabbit SERCA 1a (maximal activity < 10  $\mu M$ ). The activity of PfATP4 is resistant to inhibition by ouabain (200  $\mu M$ ) or thapsigargin (0.8  $\mu M$ ) but is inhibited by vanadate (1 mM) or cyclopiazonic acid (1  $\mu$ M). We used a quant. polymerase chain reaction to assay expression of mRNA encoding PfATP4 relative to that for  $\beta$ -tubulin in synchronized asexual stages and found variable expression throughout the life cycle with a maximal 5-fold increase in meronts compared with ring stages. This anal. suggests that PfATP4 defines a novel subclass of Ca2+-ATPases unique to apicomplexan organisms and therefore offers potential as a drug target.

Journal English LANGUAGE:

The emergence of multi-drug resistant strains of Plasmodium

falciparum and the current lack of a vaccine have stimulated research to identify new chemotherapeutic targets. The authors have focused on the isolation and

characterization of nucleotide sequences encoding putative "P"-type

cation ATPases from P. falciparum, because

selective inhibitors of mammalian members of this transporter family are well studied, and some are already in clin. use. This report describes the isolation and sequence anal. of two addnl. members of

this family, ATPases 2 and 3, and their differential

expressivity during the erythrocytic stage of parasite development. Amino acid sequence anal. identified the 7 amino acid motifs present

at the phosphorylation site (DKTGTLT) of other P-type cation

ATPases, in both clones. ATPase 2 was localized to chromosome 5 and ATPase 3 to chromosome 12 on a

Southern blot of chromosomes resolved by pulsed-field gel electrophoresis. Northern blot anal. showed that both

ATPases 2 and 3 were expressed during the erythrocytic stage of the infection. ATPase 2 has a mRNA transcript size of

5.5-6 kb and is expressed at the schizont stage of development.

ATPase 3 mRNA is approx. 5 kb in size and the strongest signal corresponds to mRNA from parasites at the ring stage of development (12-24 h postinvasion), although mRNA is also detected in all other erythrocytic stages examined

     A purified oligopeptide preparation comprising an amino acid sequence
     identical to that of a segment of a naturally-occurring human
     protein that binds to human major histocompatibility complex
     (MHC) class II allotype is provided. The human protein is
     an MHC class I or II mol., HLA-A2, invariant chain (Ii), etc.,. A
     method is described for inhibiting an immune response in a human
     patient by contacting an antigen-presenting cell (APC) of the
     patient with a therapeutic composition or an immune-stimulating
     complex (ISCOM) containing the oligopeptide, or by expression of the
     oligopeptide-coding sequence linked to a trafficking sequence in
     APCs. The oligopeptide also can be used for inducing an immune response against pathogens. The options of the oligopeptide
     delivery system is also described. Purification and characterization of 6 HLA-DR antigens (HLA-DR1.apprx.4; HLA-DR7.apprx.8) from
     Epstein-Barr virus-transformed human B lymphoblastoid cell lines
     were demonstrated.

     An actin-binding protein was purified from the
     plasmodia of a lower eukaryote, P. polycephalum, with an
     apparent mol. weight of 210 kDa on SDS-PAGE. This protein
     bound to actin filaments with a stoichiometry of 1:\overline{7}-8 in a
     Ca2+-calmodulin-dependent manner. Antibody raised against caldesmon
     from smooth muscle cross-reacted with the 210-kDa protein.
     In vitro motility assay revealed that the 210-kDa protein
     increased the sliding velocity of actin filaments on Physarum
     myosin. The 210-kDa protein more than doubled the
     actin-activated ATPase activity of Physarum myosin under
     comparative conditions of in vitro motility assay. Further
 increases in the concentration of the 210-kDa protein decreased
     its stimulatory effects. Ca2+-calmodulin prevented the
     stimulatory effects of the 210-kDa protein.
     Unexpectedly, smooth muscle caldesmon also increased the sliding
     velocity of actin filaments on smooth muscle myosin at lower concns.
     The well-known inhibitory effect of smooth muscle caldesmon on the
     actin-myosin interaction was observed with this motility assay when the
     concentration of the caldesmon was increased further. The
```

stimulatory and inhibitory effects were confirmed by measurements of actin-activated ATPase activity of smooth muscle myosin. From estns. of the intracellular concns. of the 210-kDa protein and smooth muscle caldesmon in vivo, it appears that effects of the former and the latter on actin-myosin interactions in vivo are stimulatory and inhibitory, resp.

P. falciparum digestive vacuoles containing Fe3+ oxide granules were purified from parasite homogenates by centrifugation on discontinuous sucrose gradients. Digestive vacuole membranes prepared by osmotic lysis and washed with KCl showed no detectable contamination by erythrocyte membrane proteins and only minimal contamination by nonvacuolar parasite proteins. Purified vacuolar membranes were 2.6-fold enriched in total parasite membrane ATPase activity. This ATPase was optimally active at pH  $\bar{7}$  in the presence of >2 mM Mg2+. Ca2+ and Mn2+ were .apprx.80-90% as effective as Mg2+, and Zn2+, Co2+, and Fe2+ also exerted some **stimulatory** effect. The vacuolar membrane also hydrolyzed GTP, UTP, CTP, and ADP, but AMP and 3',5'-cAMP were hydrolyzed only one-tenth as effectively as ATP. The ATPase was unaffected by vanadate, ouabain, or oligomycin but was significantly inhibited by the proton pump inhibitors NEM and NBD-Cl. Of 6 antimalarial drugs tested, quinine

The plasmodia of P. polycephalum contains large aggregates AΒ of entangled actin microfilaments. Treatment with Triton X-100 gave a demembraned cytoskeleton consisting of entangled actin filaments which showed almost no interaction with rabbit skeletal myosin. A novel actin-binding protein purified from the cytoskeleton stoichiometrically binds to actin and causes actin filaments to curl and aggregate. The protein inhibits ATPase activity as well as the superpptn. of reconstituted rabbit skeletal muscle actomyosin. This protein has a mol. weight of 36,000 and binds 7 mol of actin/mol 36,000 polypeptide.

NOVELTY - An vector comprising a heterologous nucleic acid sequence encoding an antigenic **polypeptide** and a nucleic acid molecule comprising a 3188 base pair sequence, given in the specification, a nucleic acid molecule which hybridizes to it and which encodes a protease inhibitor **polypeptide**, or nucleic acid molecules which comprise degenerate nucleic acid sequences. The vector is adapted for the expression of each **polypeptide**.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (1) inducing an immune response to an antigenic polypeptide;
  - (2) an antibody;
  - (3) a cell transformed with the novel vector;
  - (4) producing humanized or chimeric antibody;
  - (5) a hybridoma cell line which produces a monoclonal antibody;
  - (6) a vaccine comprising the novel vector; and
- (7) vaccinating an animal, preferably a human, against at least one pathological condition.

ACTIVITY - Antibacterial; Virucide; Antiparasitic; Antifungal; Anti-HIV; Antiulcer.

No biological data is given.

MECHANISM OF ACTION - Gene therapy; Vaccine.

USE - The vector is useful for preparing a composition for preventing or treating AIDS, herpes, rubeola, rubella, varicella, influenza, common cold or viral meningitis; septicemia, tuberculosis, bacteria-associated food poisoning, blood infections, peritonitis, endocarditis, sepsis, bacterial meningitis, pneumonia, stomach ulcers, gonorrhea, strep throat, streptococcal-associated toxic shock, necrotizing fasciitis, impetigo, histoplasmosis, Lyme disease, gastro-enteritis, dysentery or shigellosis; Candidiasis; or trypanosomiasis, malaria, schistosomiasis or Chagas disease (claimed).

LANGUAGE: English SUMMARY LANGUAGE: English

AB Falciparum malaria is a complex disease with no simple

explanation, affecting organs where the parasite is rare as well as those organs where it is more common. We continue to argue that it can best be understood in terms of excessive stimulation of normally useful pathways mediated by inflammatory cytokines, the prototype being tumor necrosis factor (TNF). These pathways involve downstream mediators, such as nitric oxide (NO) that the host normally uses to control parasites, but which, when uncontrolled, have bioenergetic failure of patient tissues as their predictable end point. Falciparum malaria is no different from many other infectious diseases that are clinically confused with it. The sequestration of parasitized red blood cells, prominent in some tissues but absent in others with equal functional loss, exacerbates, but does not change, these overriding principles. Recent opportunities to stain a wide range of tissues from African pediatric cases of falciparum malaria and sepsis for the inducible NO synthase (iNOS) and migration inhibitory factor (MIF) have strengthened these arguments considerably. The recent demonstration of bioenergetic failure in tissue removed from sepsis patients being able to predict a fatal outcome fulfils a prediction of these principles, and it is plausible that this will be demonstrable in severe falciparum malaria. Understanding the disease caused by falciparum malaria at a molecular level requires an appreciation of the universality of poly(ADP-ribose) polymerase-1 (PARP-1) and Na(+)/K(+)-ATPase and the protean effects of activation by inflammation of the former that include inactivation of the latter. . SUMMARY LANGUAGE: English

AB Plasmodium cynomolgi DEAD-box DNA helicase 45 (PcDDH45) is an ATP-dependent DNA-unwinding enzyme with intrinsic DNA-dependent ATPase activity and is highly homologous to eIF-4A. In this study, we have further characterized and tested the effect of various DNA-interacting compounds on the DNA-unwinding activity of PcDDH45. The results show that PcDDH45 translocates in the 3' to 5' direction along the bound strand, a replication fork-like structure of the substrate stimulates its DNA-unwinding activity, and it failed to unwind blunt-ended duplex DNA. Of various compounds

tested, only cisplatin, 4',6'-diamidino-2-phenylindole, daunorubicin, and nogalamycin were inhibitory to the unwinding activity of PcDDH45 with apparent IC(50) values of 1.0, 4.0, 7.5, and 1.7 $\mu$ M, respectively. These results suggest that the interaction of these compounds with duplex DNA generate a complex that probably impedes the translocation of PcDDH45, resulting in inhibition of unwinding activity. This study is one of the first to demonstrate the effect of various DNA-binding compounds on a malaria parasite DNA helicase and should make an important contribution to our better understanding of the nucleic acid transactions in the parasite. .COPYRGT. 2003 Elsevier Science (USA). Protozoan parasites are responsible for important diseases that AB threaten the lives of nearly one-quarter of the human population world-wide. Among them, leishmaniasis has become the second cause of death, mainly due to the emergence of parasite resistance to conventional drugs. P-glycoprotein (Pgp)-like transporters overexpression is a very efficient mechanism to reduce the intracellular accumulation of many drugs in cancer cells and parasitic protozoans including Plasmodium and Leishmania, thus conferring a multidrug resistance (MDR) phenotype. Therefore, there is a great clinical interest in developing inhibitors of these transporters to overcome such a resistance. Pgps are active pumps belonging to the ATP-binding cassette (ABC) superfamily of proteins, and consist of two homologous halves, each containing a transmembrane domain (TMD) involved in drug efflux, and a cytosolic nucleotide-binding domain (NBD) responsible for ATP binding and hydrolysis. Most conventional cancer MDR modulators interact with the drug-binding sites on the TMDs of Pgps, but they are also usually transported and the required concentrations for a permanent inhibition produce subsequent side-effects that hamper their clinical use. Besides, they only poorly modulate the

resistance in protozoan parasites. We review here a rational strategy developed to overcome the MDR phenotype in Leishmania, consisting in: i) the selection of an MDR Leishmania tropica line that overexpresses a Pgp-like transporter; ii) the use of their cytosolic NBDs as new pharmacological targets; iii) the search of new natural compounds that revert the MDR phenotype in Leishmania by binding to the TMDs; iv) the combination of subdoses of the above selected modulators directed to both targets in the transporter, NBDs and TMDs, to accumulate their reversal effects while diminishing their toxicity. In this way, we have reverted the MDR phenotype in Leishmania, including the resistance to the most promising new antileishmania agents, the alkyl-lysophospholipids. This approach might be extrapolated to be used in other eukaryotic cells.

The Apicomplexa are a phylum of diverse obligate intracellular parasites including Plasmodium spp., the cause of malaria; Toxoplasma gondii and Cryptosporidium parvum, opportunistic pathogens of immunocompromised individuals; and Eimeria spp. and Theileria spp., parasites of considerable agricultural importance. These protozoan parasites share distinctive morphological features, cytoskeletal organization, and modes of replication, motility, and invasion. This review summarizes our current understanding of the cytoskeletal elements, the properties of cytoskeletal proteins, and the role of the cytoskeleton in polarity, motility, invasion, and replication. We discuss the unusual properties of actin and myosin in the Apicomplexa, the highly stereotyped microtubule populations in apicomplexans, and a network of recently discovered novel intermediate filament-like elements in these parasites.

AB We have studied the occurrence, stage specificity and cellular location of key molecules associated with microtubules in

Plasmodium falciparum merozoites. Antibodies to

gamma tubulin, conventional kinesin and cytoplasmic dynein were used to determine the polarity of merozoite microtubules (mt), the stage specificity of the motor proteins and their location during merozoite development. We conclude that the minus ends of the mts are located at their apical pole. Kinesin was present throughout the lifecycle, appearing as a distinct crescent at the apex of developing merozoites. The vast majority of cytoplasmic dynein reactivity occurred in late merogony, also appearing at the merozoite apex. Destruction of mt with dinitroanilines did not affect the cellular location of kinesin or dynein. In invasion assays, dynein inhibitors reduced the number of ring stage parasites. Our results show that both conventional kinesin and cytoplasmic dynein are abundant, located at the negative pole of the merozoite mt and, intriguingly, appear there only in very late merogony, prior to merozoite release and invasion.

AB In plants, cytosolic inorganic pyrophosphate (PP(i)) is hydrolyzed by energy-conserving vacuolar-type H(+)-pyrophosphatases (V-PPases)

that harness the free energy of PP(i) hydrolysis to establish transmembrane H(+) gradients. Here we describe the identification and cloning of two genes, PfVP1 and PfVP2, from the malaria parasite Plasmodium falciparum. Inferred to encode type I (K(+)-dependent) and type II (K(+)-independent) V-PPases, respectively, PfVP1 and PfVP2 appeared more sequence divergent from each other than from their type I and type II counterparts in The steady state levels of PfVP1 mRNA were high in comparison to PfVP2 mRNA throughout the erythrocytic phases of infection. Western analyses of trophozoite membranes using generic V-PPase antibodies (PAB(HK) and PAB(TK)) demonstrated appreciable amounts of a Mr 67000 polypeptide whose associated aminomethylenediphosphonate- (AMDP) inhibitable PPase activity was markedly **stimulated** by K(+). Immunofluorescence microscopy of infected erythrocytes revealed PfVP antigen associated with both the parasite plasma membrane and punctate intracellular inclusions. Transient transfection of a PfVP1-GFP fusion further supported the localization of PfVP1 to the parasite plasma membrane. Based on these findings and the growth-retarding effects of AMDP, P. falciparum is concluded to possess both type I and type II V-PPases of which the former has the greatest potential for contributing to the establishment of H(+) gradients across the parasite plasma membrane under conditions of energy limitation.

\*ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS\*

AB Toxoplasma gondii, the agent causing toxoplasmosis, is an obligate intracellular protozoan parasite. A calcium signal appears to be essential for intracellular transduction during the active process of host cell invasion. We have looked for a Ca2+-transport ATPase in tachyzoites and found Ca2+-ATPase

activity (11-22 nmol Pi liberated/mg protein/min) in the tachyzoite membrane fraction, This ATP-dependent activity was stimulated by Ca2+ and Mg2+ ions and by calmodulin, and was inhibited by pomp inhibitors (sodium orthovanadate or thapsigargin). We used cytochemistry and X-ray microanalysis of cerium phosphate precipitates and immunolabelling to find the Ca2+, Mg2+-ATPase. It was located mainly in the membrane complex, the conoid, nucleus, secretory organelles (rhoptries, dense granules) and in vesicles with a high calcium concentration, Thus, Toxoplasma gondii possesses Ca2+-pump ATPase (Ca2+, Mg2+-ATPase) as do eukaryotic cells.

\*ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS\*

The addition of PPi promoted the acidification of a subcellular AΒ compartment in cell homogenates of Toxoplasma gondii tachyzoites, implying the presence of a proton-translocating pyrophosphatase. The proton gradient was collapsed by addition of the K+/H+ antiporter nigericin, and was also inhibited by addition of the PP, analogue aminomethylenediphosphonate (AMDP). Both proton transport and PPi hydrolysis were dependent upon K+, but Na+ caused partial inhibition of these activities. PPi hydrolysis was sensitive in a dose-dependent manner to AMDP, imidodiphosphate, NaF and to the thiol reagent N-ethylmaleimide. This activity was unaffected by common inhibitors of phosphohydrolases, except that NaO3V (sodium orthovanadate) stimulated the activity by 87%. Immunofluorescence microscopy, using antisera raised against conserved peptide sequences of a plant vacuolar pyrophosphatase, suggested that the pyrophosphatase in T. gondii tachyzoites was located in the plasma membrane and intracellular

vacuoles of the parasite. High-field P-31-NMR spectroscopy showed that PPi was more abundant than ATP in tachyzoites. Bisphosphonates (PPi analogues), drugs that are used in the treatment of bone diseases, inhibited proton transport and PPi hydrolysis in tachyzoite homogenates, and also inhibited intracellular proliferation of tachyzoites in tissue culture cells.

Plant vacuolar H+-translocating inorganic pyrophosphatases AB (V-PPases; EC 3.6.1.1) have been considered to constitute a family of functionally and structurally monotonous intrinsic membrane proteins. Typified by AVP1 (V. Sarafian, Y. Kim, R.J. Poole, P.A. Rea [1992] Proc Natl Acad Sci USA 89: 1775-1779) from Arabidopsis, all characterized plant V-PPases share greater than 84% sequence identity and catalyze K+-stimulated H+ translocation. Here we describe the molecular and biochemical characterization of AVP2 (accession number AF182813), a sequence-divergent (36% identical) K+-insensitive, Ca2+-hypersensitive V-PPase active in both inorganic pyrophosphate hydrolysis and H+ translocation. The differences between AVP2 and AVP1 provide the first indication that plant V-PPases from the same organism fall into two distinct categories. Phylogenetic analyses of these and other V-PPase sequences extend this principle by showing that AVP2, rather than being an isoform of AVP1, is but one representative of a novel category of AVP2-like (type II) V-PPases that coexist with AVP1-like (type I) V-PPases not only in plants, but also in apicomplexan protists such as the malarial parasite Plasmodium falciparum.

Myosin was purified to a homogeneity from sea sponge, AB Halichondria okadai. The myosin consisted of 220 kDa heavy chain, 18 kDa calcium binding light chain and 21 kDa phosphorylatable light chain. Rotary shadowed images showed the two headed myosin ( myosin II) with a 160 nm tail. The myosin was less soluble in a KCl solution as compared to rabbit skeletal myosin.

The K+-stimulated and Ca2+-stimulated ATPase activities of sea sponge myosin were 0.46 and 0.07 mu mol Pi min(-1) mg(-1), respectively. The Mg2+ activated myosin ATPase activity showed no significant enhancement by the addition of rabbit skeletal muscle actin despite that the light chain was phosphorylated by myosin light chain kinase from chicken gizzard. Sea sponge myosin 18 kDa light chain bound to Ca2+ ion but was not phosphorylated like Physarum plasmodia myosin light chains.

The human multidrug resistance protein, or P-glycoprotein (Pgp), exhibits a high-capacity drug-dependent ATP hydrolytic activity that is a direct reflection of its drug transport capability. This activity is readily measured in membranes isolated from cultured insect cells infected with a baculovirus

carrying the human mdrl cDNA. The drug-stimulated

ATPase activity is a useful alternative to conventional screening systems for identifying high-affinity drug substrates of the Pgp with potential clinical value as chemosensitizers for tumor cells that have become drug resistant. Using this assay system, a variety of drugs have been directly shown to interact with the Pgp.

Many of the drugs stimulate the Pgp ATPase activity, but certain drugs bind tightly to the drug-binding site of the Pgp without eliciting ATP hydrolysis. Either class of drugs may be useful as chemosensitizing agents. The baculovirus/insect cell Pgp ATPase assay system may also facilitate future studies

308-4994 Searcher : Shears

of the molecular structure and mechanism of the Pgp.

AB The phorbol ester TPA (phorbol 12-myristate 13-acetate) substitutes

for CO-2 as an agonist for transforming Trypanosoma cruzi

epimastigotes to the metacyclic trypomastigote stage in a starvation medium consisting of phosphate buffered saline + 10 mM proline, 10 mM sodium acetate and 0.035% NaHCO-3. Since TPA is thought to

stimulate protein kinase C by mimicking the

activity of the secondary messenger diacylglycerol, the above result suggested that T. cruzi metacyclogenesis could be activated by a

Ca-2+-dependent **protein** kinase C signal induction pathway.

Accordingly, cytosolic calcium Bux ((Ca-2+)-i) in epimastigotes, activated with 5% CO-2 or TPA (10-7 M), was measured with the Ca-2+ molecular probe, fluo-3AM. In addition, (Ca-2+)-i was measured in cells incubated with putative metacyclogenic agonists (e.g. proline, glutamate, bioamines, ionophores and catecholamines). None of the compounds studied, except for EGTA, affected cytosolic Ca-2+ levels.

Control assays with 11 mu-M thapsigargin, which mobilizes noncytoplasmic Ca-2+ stores by inhibiting endoplasmic reticulum Ca-2+-ATPase, validated our fluorometric assay procedure.

Although thapsigargin significantly increases cytoplasmic Ca-2+ fluorescence, it has no effect on transformation. The

protein kinase C inhibitors staurosporine, H-7 and HA 1004 were tested for their effect on T. cruzi metacyclogenesis. Low concentrations of staurosporine and HA 1004 significantly elevated Peru strain transformation while H-7 had no effect on Peru strain metacyclogenesis. Inhibitor H-7 did significantly depress CL

transformation. The results indicate that induction of T. cruzi metacyclic trypomastigote formation by CO-2 and TPA is not accompanied by changes in cytosolic Ca-2+ and do not provide supporting evidence for participation of a **protein** kinase C-mediated phosphoinositide cascade in metacyclogenesis.

We have purified an actin-binding protein from the AB plasmodia of a lower eukaryote, Physarum polycephalum, with an apparent molecular mass of 210,000 daltons on sodium dodecyl sulfate-polyacrylamide gel electrophoresis. This protein bound to actin filaments with a stoichiometry of 1:7-8 in a Ca(2+)-calmodulin-dependent manner. Antibody raised against caldesmon from smooth muscle cross-reacted with the 210-kDa protein. In vitro motility assay revealed that the 210-kDa protein increased the sliding velocity of actin filaments on Physarum myosin. The 210-kDa protein more than doubled the actin-activated ATPase activity of Physarum myosin under comparative conditions of in vitro motility assay. Further increases in the concentration of the 210-kDa protein decreased its stimulatory effects. Ca(2+)-calmodulin prevented the stimulatory effects of the 210-kDa protein. Unexpectedly, smooth muscle caldesmon also increased the sliding velocity of actin filaments on smooth muscle myosin at lower concentrations. The well-known inhibitory effect of smooth muscle caldesmon on the actin-myosin interaction was observed with this motility assay when the concentration of the caldesmon was increased further. The stimulatory and inhibitory effects were confirmed by measurements of actin-activated ATPase activity of smooth muscle myosin. From estimations of the intracellular concentrations of the 210-kDa protein and smooth muscle caldesmon in vivo, it appears that effects of the former and the latter on actin-myosin interactions in vivo are stimulatory and inhibitory, respectively.

AB Plasmodium falciparum digestive vacuoles

containing ferric oxide granules were purified from parasite homogenates by centrifugation on discontinuous sucrose gradients. Digestive vacuole membranes prepared by osmotic lysis and washed with KCl showed no detectable contamination by erythrocyte membrane proteins and only minimal contamination by non-vacuolar parasite proteins. Purified vacuolar membranes were 2.6-fold enriched in total parasite membrane ATPase activity. This ATPase was optimally active at pH 7 in the

Searcher: Shears 308-4994

presence of at least 2 mM Mg2+. Ca2+ and Mn2+ were approximately 80-90% as effective as Mg2+, and Zn2+, Co2+ and Fe2+ also exerted some **stimulatory** effect. The vacuolar membrane also hydrolyzed GTP, UTP, CTP and ADP, but AMP and 3',5'-cyclic AMP were hydrolyzed only one-tenth as effectively as ATP. The **ATPase** was unaffected by vanadate, ouabain or oligomycin but was significantly inhibited by the proton pump inhibitors NEM and NBD-Cl. Of 6 antimalarial drugs tested, quinine and quinacrine were the most effective inhibitors and mefloquine was the least effective.

AB The actomyosin protein complex of Physarum polycephalum was prepared from vegetative and starved plasmodia. The yield of actomyosin per unit wet wt was the same from both types of plasmodia. Myosin was resolved from the complex by gel filtration and purified by ion exchange chromatography. The Ca2+

stimulated adenosine triphosphatase
activities of myosin preparations from vegetative and starved
plasmodia were not appreciably different. Synthesis of
myosin de novo was shown to occur during the starvation phase of the
life cycle by the isolation of labelled myosin preparations from
plasmodia starved in the presence of [2 14C]glycine.
Fractionation of polyacrylamide gels after gel filtration of
labelled myosin confirmed the presence of label in the
adenosine triphosphatase active myosin band. It is
concluded that during starvation myosin synthesis continues although
there is a net loss of approx. 50% of the total protein.
Sodium dodecyl sulphate polyacrylamide gel electrophoresis of
Physarum myosin showed the presence of low molecular weight
components of the molecule, similar to those of muscle myosins. The
content and composition of the free amino acid pool to Physarum was

- Plasmodium falciparum infection induces alterations in the transport properties of infected erythrocytes that have recently been defined using electrophysiological techniques. Mechanisms responsible for transport of substrates into intraerythrocytic parasites have also been clarified by studies of three substrate-specific (hexose, nucleoside and aquaglyceroporin) parasite plasma membrane transporters. These have been characterised functionally using the Xenopus laevis oocyte heterologous expression system. The same expression system is currently being used to define the function of parasite 'P' type ATPases responsible for intraparasitic [Ca(2+)] homeostasis. We review studies on these transport processes and examine their potential as novel drug targets.

- We report the nucleotide sequence, derived amino acid sequence and AB expression profile of P-type ATPase 3 (PfATPase3) from Plasmodium falciparum. An open reading frame of 7362 nucleotides, interrupted by a single intron of 168 nt, encoded a protein product of 2394 amino acids with a predicted MW of 282791 Da. Hydropathy analysis of PfATPase3 revealed six amino-terminal and six carboxyl-terminal membrane spanning regions (M1-12) flanking a large hydrophilic domain with a smaller hydrophilic loop between M4 and M5. Based on a phylogenetic comparison of conserved domains present in P-type ATPases from other organisms, PfATPase3 resembled a Type-V ATPase for which the transport affinity is unknown. The PfATPase3 topology was interrupted by four regions, termed 'inserts', unique to malarial P-type ATPases, which were high in asparagine residues and charged amino acids (inserts I1-I4). Inserts I1 and I3 also contained repeated amino acid motifs. The number and composition of repeated amino acid motifs in insert I3 were variable in seven P. falciparum strains tested. PfATPase3 was 80.2% similar to the non-insert portions of P. yoelii ATPase3, although their inserts differed in length and composition. PfATPase3 mRNA was most abundant relative to beta-tubulin during the latter half of the erythrocytic cycle and was also present in gametocytes. Using affinity-purified antibody to a 14 amino acid PfATPase3 epitope, a 260 kDa protein was detected by Western analysis. Based on immunofluorescence, the PfATPase3 protein was located intracellularly in gametocytes and, to a lesser extent, in late erythrocytic stages.

- AΒ Certad, G., Abrahem, A., and Georges, E. 1999. Cloning and Partial characterization of the proteasome S4 ATPase from Plasmodium falciparum. Experimental Parasitology 93, 123-131. ATP-ubiquitin-proteasome pathway mediates the nonlysosomal degradation of cytosolic proteins in eukaryotic cells. The activities of this pathway have been shown to regulate cell growth and differentiation through modulation of regulatory proteins. The proteasome is a large complex consisting of two multisubunit structures, the 20S and 19S(PA700) or P28 complexes, that combine to form the 26S particles. In this study, we describe the cloning of a cDNA encoding the proteasome subunit 4 ATPase homologue from Plasmodium falciparum (PFS4). Analysis of the PFS4 cDNA sequence shows an open reading frame encoding a deduced protein of 455 amino acids. Moreover, comparison of PFS4 cDNA sequence to that of genomic fragments encoding PFS4 showed identical sequences with no detectable introns. Database searches revealed a high sequence identity to those of rice, yeast, mouse, Drosophila, and human S4 ATPases. However, PFS4 contains two unique inserts of nine and seven amino acid residues in the N-terminal domain. Interestingly, only the rice S4 contains the latter (seven amino acids) insert with four identical amino acids. In vitro expression of the full-length cDNA encoding the PFS4, using a transcription-translation-coupled reticulocyte lysate, shows a 50-kDa [(35)S]methionine-labeled protein which was immunoprecipitated with PFS4 anti-peptide antiserum. Southern blot analysis of genomic DNA digests shows a single gene copy of PFS4 in P. falciparum. Of interest was the effect of the proteasome-specific natural product, lactacystin, on the growth of the parasite, with IC(50) values of 0.6-0.92 microM. The latter IC(50) values of lactacystin for different clones of P. falciparum are comparable to those obtained for mammalian cell lines (0.65 microM), suggesting the presence of a conserved proteasome complex. Moreover, lactacystin was equally toxic to drug-sensitive and resistant parasites. Copyright 1999 Academic Press.

- AB A Plasmodium falciparum homologue of one of the components of a chromatin-remodelling complex which controls binding of transcription factors to nucleosome core particles has been cloned and characterised. The gene encodes 1422 amino acids with an estimated molecular mass of 167 kDa. The protein, SNF2L, shares 60% amino acid identity in its conserved DNA-dependent ATPase domain with yeast transcription factors originally identified by characterising mating type switch mutants. It also contains sequences related to the so-called SWI3, ADA2, N-CoR and TFIIIB B" or SANT DNA binding domains which are characteristic of these transcriptional activation factors. The SNF2L gene has two short introns in the 3' region of the coding sequence of the gene and is transcribed into a single approximately 6.5 kb messenger RNA species which is present throughout the asexual stages of the cell cycle. Southern blotting and pulsed field gel electrophoresis experiments show that SNF2L is a single copy gene. located on P. falciparum chromosome 11.

- We have cloned and characterised one gene, PfATPase4 which encodes a AB P-type ATPase containing all the primary sequence motifs characteristic of this class of transmembrane ion transporters, and also a fragment of a second P. falciparum P-type ATPase pseudogene (PfATPase5). Analysis of conserved domains and motifs of specific ATPases reveals that PfATPase4 is most analogous to Ca2+ ATPases of the endoplasmic reticulum. The PfATPase4 gene gives rise to a transcript of 8 kb shortly after erythrocyte invasion. Although this mRNA is not detected in later stages, the protein detected immunologically at 190 kDa persists throughout and is detected in free merozoites. Immunofluorescence microscopy reveals that the PfATPase4 protein is concentrated in discrete compartments at the periphery of the parasite. Detailed sequence and structural analyses of these and the other P-type ATPases of P. falciparum described previously, reveals that they comprise an unusual family in several respects. Firstly, the large number of non-homologous genes so far characterised reflects the complexities of ionic regulation in the diverse environments encountered by the parasite. Secondly, the plasmodial P-type ATPase family may be classified both at primary sequence and structural levels into two distinct groups-those typical of P-type ATPases (including PfATPase4) and those which are much more divergent. A third complexity is illustrated by the fact that one of the other members [1] here termed PfATPase6, has an even greater similarity to the sarcoplasmic reticulum Ca2+ ATPases than does PfATPase4, which raises questions about the possible functional relationship between these two members.

- AB In order to study molecules that may be involved in pH gradient formation in Plasmodium, we have identified a novel cation-translocating ATPase (P-type ATPase) gene from P. falciparum (Pf). We report the full-length nucleotide and deduced amino acid (aa) sequences of this gene that we called PfATPase4. The PfATPase4 protein shares features with the different members of eukaryotic P-type ATPases, such as a similar transmembrane (TM) organization and aa identity in functionally important regions. Interestingly, the PfATPase4 protein possesses conserved aa involved in calcium binding in mammalian organellar Ca(2+)-ATPases.

- AB We have identified two novel P-type ATPase genes from Plasmodium falciparum and report the full-length nucleotide and derived amino acid sequence of the ATPase2 gene from P. falciparum (PfATPase2). PfATPase2 is phylogenetically remote from the different members of prokaryotic and mammalian P-type ATPases but shares features with a putative membrane-spanning Ca2+ ATPase involved in ribosome function in yeast. PfATPase2 is expressed during the intraerythrocytic life cycle of the parasite and appears to be required in the late stages of its asexual development. We also present the partial sequence of another malarial gene displaying sequence similarity with the family of P-type transporting ATPases (PfATPase4). We have analysed the organisation of the genes encoding the P-type ATPases of P. falciparum and show that they are a highly dispersed gene family.

- The transvacuolar pH gradient determines, to a significant extent, the distribution of the antimalarial drug chloroquine in Plasmodium falciparum. A proton pump, similar to the vacuolar ATPase found in many cell types, appears to regulate a pH gradient across the membranes of acidic compartments of the parasite. In order to understand and define the components involved in the maintenance of the vacuolar pH gradient, we have cloned and characterized a gene, designated VAP B, encoding a P. falciparum homologue of the B subunit of the vacuolar ATPase. The VAP B gene encodes a protein of 494 amino acids which has between 69% and 74% amino acid identity with the sequences of vacuolar ATPase B subunits of other organisms. The VAP B gene exists as a single copy gene on chromosome 4 that gives rise to a RNA transcript of 2.4 kb. Antibodies raised to the

VAP B protein react specifically with a protein of 56-kDa, consistent with the size predicted from the gene sequence and with the homologous protein from other organisms. The 56-kDa protein is expressed throughout the asexual life cycle and subcellular localization by indirect immunofluorescence shows that the protein has a heterogeneous distribution over most of the parasite. This suggests that the function of the vacuolar proton ATPase is not confined to the regulation of the pH of the digestive vacuole.

- The distribution of the antimalarial drug chloroquine is determined AB to a significant extent by a transvacuolar pH gradient in Plasmodium falciparum. A proton pump similar to the vacuolar ATPase found in many cell types has been suggested to maintain a pH gradient across the membranes of acidic compartments in the parasite. In order to understand and define the components involved in the mechanism of acidification of parasite vesicles, we have cloned and characterized a gene, designated VAP-A, encoding a P. falciparum homologue of the catalytic A subunit of the vacuolar ATPase. The VAP-A gene encodes a polypeptide of 611 amino acids which shows between 56 to 61% amino acid identity over its entire length with the sequences of vacuolar ATPase A subunits from several species. The VAP-A gene exists as a single copy gene on P. falciparum chromosome 13 and gives rise to a transcript of 3.7 kb. Antibodies raised against a VAP-A gene segment expressed in Escherichia coli react specifically with a 67-kDa polypeptide, consistent with the size predicted from the sequence and with the size of the corresponding polypeptide in other organisms. The 67-kDa protein is present throughout the asexual erythrocytic cycle and is expressed at similar levels in 5 P. falciparum isolates of differing chloroquine sensitivity. Sequence analysis of the coding region of the VAP-A gene from 2 chloroquine-sensitive and 3 chloroquine-resistant isolates has shown no changes that are linked to chloroquine resistance. Therefore, a proposed chloroquine resistance-linked vacuolar acidification defect does not involve mutations in the VAP-A gene in the isolates we have studied.

- AB We report the nucleotide and derived amino acid sequence of the

ATPase 1 gene from Plasmodium falciparum. The amino acid sequence shares homology with the family of "P"-type cation translocating ATPases in conserved regions important for nucleotide binding, conformational change, or phosphorylation. The gene, which is present on chromosome 5, has a product longer than any other reported for a P-type ATPase. Interstrain analysis from 12 parasite isolates by the polymerase chain reaction reveals that a 330-bp nucleotide sequence encoding three cytoplasmic regions conserved in cation ATPases (regions a-c) is of constant length. By contrast, another 360-bp sequence which is one of four regions we refer to as "inserts" contains arrays of tandem repeats which show length variation between different parasite isolates. Polymorphism results from differences in the number and types of repeat motif contained in this insert. Inserts are divergent in sequence from other P-type ATPases and share features in common with many malarial antigens. Studies using RNA from the erythrocytic stages of the malarial life cycle suggest that ATPase 1 (including the sequence which encodes tandem repeats) is expressed at the large ring stage of development. Immunolocalization has identified ATPase 1 to be in the region of the parasite plasma membrane and pigment body. These findings suggest a possible model for the genesis of malarial antigens.

- Chloroquine inhibits the growth of susceptible malaria parasites at AB low (nanomolar) concentrations because of an energy-requiring drug-concentrating mechanism in the parasite secondary lysosome (food vacuole) which is dependent on the acidification of that vesicle. Chloroquine resistance results from another energy-requiring process: efflux of chloroquine from the resistant parasite with a half-time of 2 min. Chloroquine efflux is inhibited reversibly by the removal of metabolizable substrate (glucose); it is also reduced by the ATPase inhibitor vanadate. These results suggest that chloroquine efflux is an energy-requiring process dependent on the generation and hydrolysis of ATP. Chloroquine efflux cannot be explained by differences in drug accumulation between chloroquine-susceptible and -resistant parasites because the 40-50-fold difference in initial efflux rates between -susceptible and -resistant parasites is unchanged when both parasites contain the same amount of chloroquine. Although chloroquine efflux is phenotypically similar to the efflux of anticancer drugs from multidrug-resistant (mdr) mammalian cells, it is not linked to either of the mdr-like genes of the parasite.

- AB Chloroquine susceptibility and resistance have been associated respectively with the uptake and efflux of chloroquine by Plasmodium falciparum. We made membrane preparations from parasitized and unparasitized red cells in order to study chloroquine accumulation in a cell-free system. The accumulation of [3H]chloroquine by these preparations is inhibited by unlabeled chloroquine and thus is specific. Only membranes from parasitized red cells demonstrate time-dependent chloroquine accumulation; membranes from unparasitized red cells do not. Chloroquine accumulation is eliminated by detergent (0.05% Triton X-100) and reduced by a hypertonic medium, consistent with accumulation inside membrane vesicles rather than binding to membranes. Accumulation is energy dependent; it has a specific requirement for ATP, which cannot be replaced with GTP, CTP, UTP, TTP or ADP, an apparent Km of 21 microM and an apparent Vmax of 4.6 pmol (mg protein)-1 h-1. Vesicle acidification is MgATP dependent, and is reversed by NH4Cl. Chloroquine accumulation is inhibited by reduced medium pH, N-ethylmaleimide or oligomycin, but not by vanadate or ouabain. These studies demonstrate that membrane vesicles prepared from parasitized red cells provide a model system for the study of chloroquine accumulation by P. falciparum.

- SO BLOOD CELLS, (1990) 16 (2-3) 437-49. Ref: 61 Journal code: 7513567. ISSN: 0340-4684.
- AΒ Malaria parasites of the genus Plasmodium spend much of their asexual life cycle inside the erythrocytes of their vertebrate Parasites presumably have to exploit metabolic and transport. mechanisms to adapt themselves to the host erythrocyte's physicochemical environment. This review surveys the metabolism and transport of Ca2+, alkali cations, and H+ in malaria-infected erythrocytes. The Ca2+ content of Plasmodium-infected erythrocytes increases as the parasite matures. An increase in the influx of extracellular Ca2+ into infected erythrocytes is evident at later stages of parasite development. In infected erythrocytes, Ca2+ is almost exclusively localized in the parasite compartment and changes but little in the cytosol of the host cell. The importance of Ca2+ in supporting the growth of intraerythrocytic parasites and the invasion of erythrocytes by the merozoite has been assessed by depletion of extracellular Ca2+ with chelators, or by disturbance of the metabolism and transport of Ca2+ with a variety of Ca2+ modulators. Membranes of malaria-infected erythrocytes change their permeability to alkali cations. Hence, levels of K+ decrease and levels of Na+ increase in the cytosol of infected erythrocytes. Intraerythrocytic parasites maintain a high K+, low Na+ state, suggesting a mechanism for transporting K+ inward and Na+ outward against concentration gradients of the alkali cations across the parasite plasma membrane and/or the parasitophorous vacuole membrane (PVM). Concomitantly, P. falciparum can grow in Na(+)-enriched human erythrocytes. Experimental evidence suggests that Plasmodium possesses in its plasma membrane a proton pump which is very sensitive to orthovanadate, carbonylcyanide m-chlorophenylhydrazone, a protonophore, and dicyclohexylcarbodiimide, an inhibitor of H(+)-ATPase, but is only slightly sensitive to inhibitors of bacterial and mitochondrial respiration, such as antimycin A, CN-,

or N3-, and ouabain, a Na+, K(+)-ATPase inhibitor. By operating this proton pump, parasites extrude H+ and thus generate an electrochemical gradient of protons (an internal negative membrane potential and a concentration gradient of protons) across the parasite plasma membrane. The electrochemical gradient apparently drives inward movement of Ca2+ and, possibly, glucose from the cytosol of infected erythrocytes. Little is known about the transport properties of the PVM. Recent sequence studies suggest that Plasmodium contains a cation-transporting ATPase which exhibits a high homology to the Ca2(+)-ATPase of rabbit skeletal muscle sarcoplasmic reticulum. - AΒ Plasmodium falciparum digestive vacuoles containing ferric oxide granules were purified from parasite homogenates by centrifugation on discontinuous sucrose gradients. Digestive vacuole membranes prepared by osmotic lysis and washed with KCl showed no detectable contamination by erythrocyte membrane proteins and only minimal contamination by non-vacuolar parasite proteins. Purified vacuolar membranes were 2.6-fold enriched in total parasite membrane ATPase activity. This ATPase was optimally active at pH 7 in the presence of at least 2 mM Mg2+. Ca2+ and Mn2+ were approximately 80-90% as effective as Mg2+, and Zn2+, Co2+ and Fe2+ also exerted some stimulatory effect. The vacuolar membrane also hydrolyzed GTP, UTP, CTP and ADP, but AMP and 3',5'-cyclic AMP were hydrolyzed only one-tenth as effectively as ATP. The ATPase was unaffected by vanadate, ouabain or oligomycin but was significantly inhibited by the proton pump inhibitors NEM and NBD-Cl. Of 6 antimalarial drugs tested, quinine and quinacrine were the most effective inhibitors and mefloquine was the least effective.

NOVELTY - An isolated microtubule motor protein, which has greater than 70 % sequence identity to a 1368 amino acid sequence (P1), given in the specification as measured using a sequence comparison algorithm, is new.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (1) an isolated nucleic acid sequence:
- (a) encoding the microtubule motor protein described above, where the motor the protein's activity includes microtubule depolymerization activity; or
- (b) comprising a sequence which has greater than 60 % sequence identity with nucleotide comprising 6409 base pairs (N1), given in the specification;
- (2) an expression vector comprising the nucleic acid encoding the microtubule motor protein;
  - (3) a host cell transfected with the vector of (2);
  - (4) screening for modulators of KinI-3 comprising:
  - (a) providing the biologically active KinI-3;
- (b) contacting the biologically active KinI-3 with a candidate agent in a test and control concentration; and
- (c) assaying for the level of KinI-3 activity, where the KinI-3 activity consists of binding activity or ATPase activity, and where a change in activity between the test and control concentration indicates a modulator; and
- (5) a compound that modulates KinI-3, which is identified using the method of (4).

ACTIVITY - Cytostatic; Vasotropic; Immunomodulator; Antiinflammatory; Vulnerary; Antirheumatic; Antiarthritic; Antiarteriosclerotic; Antigout; Antipsoriatic; Antidiabetic; Ophthalmological; Immunosuppressive; Neuroprotective.

No biological data is given.

MECHANISM OF ACTION - ATPase Modulator; Microtubule Motor Protein Modulator.

USE - The KinI-3 protein, nucleic acid, or its modulator, is useful for diagnosing, preventing or treating cellular proliferation

> Searcher : Shears 308-4994

(e.g. cancers (e.g. bronchogenic, carcinoma, Kaposi's sarcoma, lymphoma, leukemia, osteoid osteoma, glioblastoma, etc.), hyperplasia, restenosis, cardiac hypertrophy, immune disorders or inflammation), neurological disorders, or disorders of vesicular transport. These disorders also include atherosclerosis, hemangiomas, acoustic neuromas, vascular malfunctions, abnormal wound healing, rheumatoid arthritis, Bechet's disease, gout, psoriasis, diabetic retinopathy, corneal graft rejection, glaucoma, Osler Webber syndrome, etc. The protein, nucleic acid or the KinI-3 modulator regulates cell cycle, as well as cellular proliferation. The KinI-3 protein or nucleic acid is also useful for screening therapeutic agents or KinI-3 modulators, which may be used for treating the above-mentioned diseases or disorders.

Whereas most kinesins motor along microtubules, KinI kinesins are microtubule depolymg. machines. Surprisingly, we found that a KinI fragment consisting of only the motor core is capable of ATP-dependent depolymn. The motor binds along microtubules in all nucleotide states, but in the presence of AMPPNP, microtubule depolymn. also occurs. Structural characterization of the products of AMPPNP-induced destabilization revealed a snapshot of the disassembly machine in action as it precisely deformed a tubulin dimer. While conventional kinesins use the energy of ATP binding to execute a "power-stroke," KinIs use it to bend the underlying protofilament. Thus, the relatively small class-specific

differences within the KinI motor core modulate a fundamentally conserved mode of interaction with microtubules to produce a unique depolymg. activity.

Artemether, an efficacious antimalarial drug, effectively ΔR prevents patent schistosome infections and morbidity, as established in laboratory models and in clinical trials. In view of concern about the potential long-term toxicity, rats were treated orally with 80 mg/kg artemether once every 2 weeks for 5 months. After the final treatment, routine blood test results were normal except for reversible reductions of reticulocyte counts and reversible increases in hemoglobin levels. Liver and kidney function and histopathological examination showed no differences between treated and untreated rats. Administration of 400 mg/kg artemether resulted in transient focal vesicle degeneration of the liver or slight damage to the proprius layer lamina of intestinal villi. No damage to the central nervous system tissues, including cerebrum, cerebellum, midbrain, thalamus, pons, medulla oblongata, and spinal cord, was seen at either concentration. There were no alterations in electrocardiograms during the 6-month treatment period. We conclude that 80 mg/kg artemether administered once every 2 weeks is safe, and doses of 400 mg/kg do not result in evidence of neurotoxicology.

\*ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS\*

AB A statistical sampling protocol is described to assess the fidelity of libraries encoded with molecular tags. The methodology, termed library QA, is based on the combined application of tag decode analysis and single bead LC/MS. The physical existence of library compounds eluted from beads is established by comparing the molecular weight predicted by tag decode with empirical measurement. The goal of sampling is to provide information on overall library fidelity and an indication of the performance of individual library synthons. The minimal sampling size n for library QA is 10x the largest synthon set. Data are reported as proportion (p) +/- lower and upper boundary (1b-ub) computed at the 95% confidence level (alpha = 0.05). As a practical demonstration, library QA was performed on a 25 200-member library of statine amides (size = 40 x $63 \times 10$ ). Sampling was conducted three times at n similar to 630beads per run for a total of 1902 beads. The overall proportions found for the three runs were consistent with one another: p =84.4%, 1b-ub = 81.5-87.2%; p = 83.1%, 1b-ub = 80.2-85.95; and p = 81.5-87.2% 84.5%, 1b-ub = 81.8-87.3%, suggesting the true value of p is close to 84% compound confirmation. The performance pi of individual synthons was also computed. Corroboration of QA data with biological screening results obtained from assaying the library against cathepsin D and plasmepsin II is discussed.

AB The effect of sodium artesunate on Plasmodium yoelii-infected mouse erythrocytes was analysed by flow cytometry. The results showed that malarial DNA content in experimental group was obviously decreased 2-5 hours after the drug was administered, fluorescence distribution of malarial DNA almost disappeared within 24 hours after the administration. Thus we deem that sodium artesunate can inhibit the DNA synthesis in P. yoelii.
